

G52DOA - Derivation of Algorithms

Lecture 1

Venanzio Capretta

Nottingham, Thursday 4 February 2010

The correctness of programs

What is the topic of this course?

- ▶ Programs written in C, Java, or other imperative languages are often full of bugs;
- ▶ Debugging by testing: A finite number of tests can never guarantee absolute correctness;
- ▶ Instead we give a logico/mathematical proof of correctness;
- ▶ Specification: Express precisely what the program is supposed to do;
- ▶ Verification: Prove formally that the program satisfies the specification;
- ▶ Derivation: Start with the specification and build from it a program that is correct by construction.

Dictionary Search

How to search a word W in a dictionary:

- ▶ Open at random page;
- ▶ Check the first (F) and last (L) word of page;
- ▶ If W comes between F and L, we found it;
- ▶ Otherwise:
 - ▶ If W comes before F: discard pages on the right;
 - ▶ If W comes after L: discard pages on the left;
 - ▶ Start again from beginning.

Variables of the algorithm

The dictionary is always divided in three parts:

- ▶ The discarded left part;
- ▶ The discarded right part;
- ▶ The active part: where we are searching.

We also need a variable for the randomly chosen page in the searching part.

- ▶ Searched word: w ;
- ▶ Left limit of active part: l ;
- ▶ Right limit of active part: r ;
- ▶ Randomly chosen page of the active part: p .

More precise algorithm

- ▶ input w ;
- ▶ $l := \text{first page}$;
- ▶ $r := \text{last page}$;
- ▶ $p := \text{random page between } l \text{ and } r$;
- ▶ repeat while w is not on p :
 - ▶ if w comes before the first word of p , $r := \text{page before } p$;
 - ▶ if w comes after the last word of p , $l := \text{page after } p$;
 - ▶ $p := \text{random page between } l \text{ and } r$;

Specification

What does it mean for this algorithm to be correct?

Assuming that, before the execution,
the following proposition (P) is true:

- ▶ The dictionary is in alphabetical order,
- ▶ w is in the dictionary;

Then, after the execution,
the following proposition (Q) is true:

- ▶ w is on page p,
- ▶ the value of w has not changed.

P is called a **precondition** of the program.

Q is called a **postcondition** of the program.

Write pre- and post- condition in curly brackets before and after the program, respectively:

- ▶ input w;
 {dictionary ordered, w in dictionary, w=W}
- ▶ l:= first page;
- ▶ r:= last page;
- ▶ p:= random page between l and r;
- ▶ repeat while w is not on p:
 - ▶ if w comes before the first word of p, r := page before p;
 - ▶ if w comes after the last word of p, l := page after p;
 - ▶ p:= random page between l and r;
- {w on p, w=W}

To prove that the program satisfies this specification:
Insert other propositions ([assertions](#)) inside the program.

Annotated Program

- ▶ input w ;
 $\{\text{dictionary ordered, } w \text{ in dictionary, } w=W\}$
- ▶ $l := \text{first page}$;
- ▶ $r := \text{last page}$;
- ▶ $p := \text{random page between } l \text{ and } r$;
 $\{w \text{ on } p \text{ or } w \text{ in } [l..p) \text{ or } w \text{ in } (p..r], w=W\}$
- ▶ repeat while w is not on p :
 $\{\text{Invariant: } w \text{ on } p \text{ or } w \text{ in } [l..p) \text{ or } w \text{ in } (p..r], w=W\}$
 - ▶ if w comes before the first word of p , $r := \text{page before } p$;
 - ▶ if w comes after the last word of p , $l := \text{page after } p$;
 - ▶ $p := \text{random page between } l \text{ and } r$;
- $\{w \text{ on } p, w=W\}$

Invariant: we mean that this proposition is true at the beginning of the loop and it remains true after every iteration of the loop.
